#### What is a perovskite?

A perovskite is a crystal structure, that features unique dielectric properties.

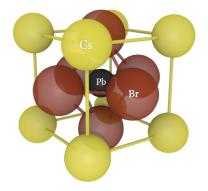

Figure 1: Illustration of the perovskite structure with the CsPbBr<sub>3</sub> perovskite as example.

- Perovskite is the retained name for CaTiO<sub>3</sub>. Calling a material a perovskite refers to its crystal structure being the same as for CaTiO<sub>3</sub>.
- A perovskite has a structure of ABX<sub>3</sub>.
- Nobel price for the first high temperature super conductor.
- High electric conductivity and high absorbance.

# Basic OLED stack design

An Organic Light-Emitting Diode (OLED) consists of anode, cathode and functional organic layers in between.

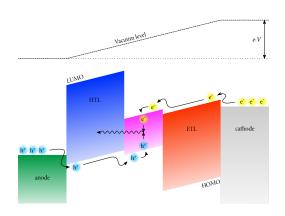

Figure 2: Simplified illustration of processes, leading to light emission, in OLEDs.

- Electrons and holes are injected by the cathode and anode respectively.
- The ETL and HTL have high mobilities for the respective charge carrier.
- Charge carriers meet to form excitons, which will decay with the emission of a photon.

# Developing a suitable hole injection site

poly-TPD has several potential advantages for application in a perovskite based OLED.

#### Using poly-TPD as additional HIL<sup>a</sup> has advantages:

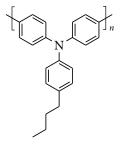

Figure 3: poly-TPD

- Optical optimization by controlling interference effects.
- Electron blocking ability, due to a high LUMO<sup>b</sup>.
- Dried film insoluble to most solvents.
- Enhanced hole injection properties in low HOMO<sup>c</sup> emitting materials, enabled by a low HOMO of poly-TPD itself.
- Chemical shielding between the HIL underneath and the layer above.

aHIL = hole injection layer

b LUMO = lowest unoccupied molecular orbital

CHOMO = highest occupied molecular orbital

Introduction

# Investigation on optical properties of (MA)PbI<sub>3</sub>

The optical properties are well-suited to verify a perovskite formation.

#### **Experimental Details:**

- Precursors PbI<sub>2</sub> and (MA)I<sup>a</sup> have been dissolved in DMF<sup>b</sup> with 1 M concentration.
- Two solutions have been chosen for the experiment:
  - ▶ PbI<sub>2</sub> in DMF (1 M).
  - ▶ PbI<sub>2</sub> in DMF (1 M) and (MA)I in DMF (1 M) mixed at 1:1 ratio (volumetric).
- The solutions are spin coated at 5000 rpm for 30 seconds on glass substrates and subsequently heated to 90°C for 5 minutes.
- The reflexion and transmission is measured in air.

a MA = Methylammonium

bDMF = Dimethylformamide

# Investigation on optical properties of (MA)PbI<sub>3</sub>

The the optical properties of PbI<sub>2</sub> are negligible for the mixed solvent's sample, indicating a full (MA)PbI<sub>3</sub> perovskite formation with few residual PbI<sub>2</sub>.

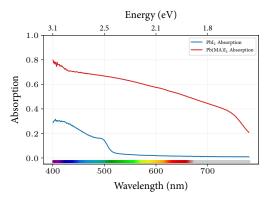

Figure 4: Absorption spectra measured by a spectrophotometer.

- The PbI<sub>2</sub> absorbs light of wavelengths smaller then 500 nm, which is plausible when comparing with the yellowish color of the film.
- The (MA)PbI<sub>3</sub> film is absorbing in the whole visible spectrum, which is quite expected, since the film had a black color.
- The characteristic trait of (MA)PbI<sub>3</sub> to have blackish color respectively having high absorbance can be verified.<sup>[1]</sup>

### Introduction of (MA)PbI<sub>3</sub> into an OLED stack

A standard electron injection site has been chosen, for hole injection the poly-TPD-based system has been applied.

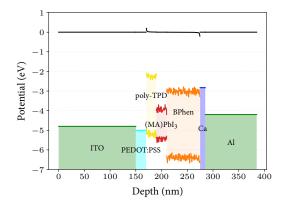

Figure 5: Schematic energy band diagram of the first (MA)PbI<sub>3</sub>-based OLED sample.<sup>[2-8]</sup>

- The hole injection is performed by a PEDOT:PSS and poly-TPD layer of total thickness of 40 nm
- The emitter is deposited by two different procedures.
  - The one-step-process: deposition by a (MA)PbI<sub>3</sub> solution.
  - The two-step-process: subsequent deposition of PbI<sub>2</sub> and (MA)I.
- For electron injection a 70 nm thick BPhen<sup>a</sup> layer was used.

 $<sup>^{\</sup>mathrm{a}}$ Bathophenanthroline

# Introduction of (MA)PbI<sub>3</sub> in an OLED stack

The (MA)PbI<sub>3</sub> is deposited in two different ways, yielding comparable results.

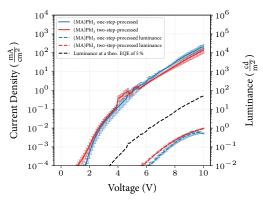

Figure 6: Current density and luminance versus driving voltage characteristics of the (MA)PbI<sub>3</sub> based OLEDs.

- The two-step-processed OLED shows higher luminance for lower currents.
- The OLED shows no (plain eyed) visible luminance. However devices detect a luminance.

### Introduction of (MA)PbI<sub>3</sub> in an OLED stack

(MA)PbI<sub>3</sub>'s luminance is at wavelengths reaching the infrared domain.

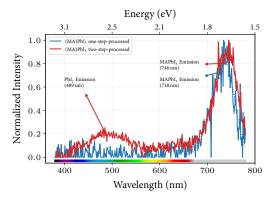

Figure 7: Electroluminescent spectrum of the (MA)PbI<sub>3</sub> based OLEDs.

- The spectrum explains why its is hard to see with plain eye. The human eye has poor sensitivity at near infrared wavelengths.
- An emission of energies around 1.5 eV is expected, by the (MA)PbI<sub>3</sub>'s HOMO (5.4 eV<sup>[5]</sup>) and LUMO (3.9 eV<sup>[5]</sup>).
- The green emission can be ascribed to the PbI<sub>2</sub>. Which can only be identified in the two-step-processed OLED.

# Summary on (MA)PbI<sub>3</sub> films and OLEDs

#### • (MA)PbI<sub>3</sub> films:

- ightharpoonup A perovskite consisting of PbI<sub>2</sub> and (MA)I, (MA)PbI<sub>3</sub>, can be synthesized.
- ► The absorption of (MA)PbI<sub>3</sub> covers the whole spectrum, increasing towards lower wavelengths.
- ► The (MA)PbI<sub>3</sub> surfaces are partly rough and holey.
- ► Solution processing on hot grounds renders the film more closed.

#### • (MA)PbI<sub>3</sub> based OLEDs:

- The manufactured devices work at low perforance, sufficiently for a proof of concept.
- ► The emission maximum is located at the visible spectrum threshold to the infrared spectrum.
- ► For actual light-emitting diodes material systems like (MA)PbBr<sub>3</sub>, are more suited to characterize.

Introduction

### Charaterisation of CsPbBr<sub>3</sub> layers

The surface texture and the layer thickness are to be determined.

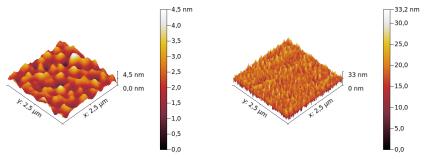

#### **Experimental Details:**

- The CsPbBr<sub>3</sub> quantum dots are present in unknown concentration solved in toluene
- The solution can be diluted and spin coating speeds can be adjusted.
- Layers of interest are the one grown on poly-TPD. So the standard PEDOT:PSS + poly-TPD layers are applied before spincoating the CsPbBr<sub>3</sub> quantum dots.
- The AFM and profilometer measurement is performed in air.

### Atomic Force Microscopy of CsPbBr<sub>3</sub> layers

The surface texture is controlled by concentration and spin-coating speed.

- (a) Surface morphology of a CsPbBr<sub>3</sub> quantum dots solution spin-coated at 5000 rpm on a poly-TPD coated substrate.
- (b) Surface morphology of a CsPbBr<sub>3</sub> quantum dots solution spin-coated at 5000 rpm on a PMMA coated substrate.

Figure 7: AFM images of CsPbBr<sub>3</sub> quantum dot solutions spin-coated on organic layers.

### Benchmark of the carrier injection in the OLED.

The charge carrier transport layers are tested with a well known phosphorent emitter.

 The CBP<sup>a</sup>:Ir(ppy)<sub>3</sub><sup>b</sup> Host-Emitter system is known to have a high efficiency.

 A doping ratio of 8% Ir(ppy)<sub>3</sub> to CBP has been determined to be the most efficient by colleages of the chair.

Figure 8: Schematic energy band diagram of the reference OLED sample. [9, 10]

<sup>&</sup>lt;sup>a</sup>CBP = 4,4'-Bis(N-carbazolyl)-1,1'-biphenyl

b Tris[2-phenylpyridinato-C2,N]iridium(III)

### Benchmark of the carrier injection in the OLED.

The CBP:Ir(ppy)<sub>3</sub> device is performing well; so the charge transport layers do not have inheritely an issue.

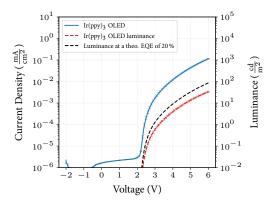

Figure 9: Current density and luminance versus driving voltage characteristics of the Ir(ppy)<sub>3</sub>-based OLED.

- The luminance is about half as high as the one for an ideal (isotropic) phosphorent emitter.<sup>a</sup>
- Around the onset the sample is nearly ideal.
- No fast degradation for driving voltages up to 10 V can be observed.

 $<sup>^{\</sup>mathrm{a}}$  A theoretical device with a constant EQE of 20 %, the same voltage-current dependence, and the same emission spectrum.

### Introduction of CsPbBr<sub>3</sub> in an OLED stack

For electron injection an  $Alq_3$ -OXD7 based system, and for hole injection the poly-TPD-based system has been applied.

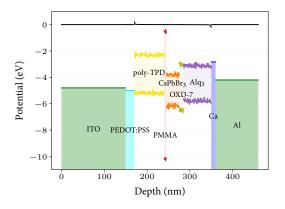

Figure 10: Schematic energy band diagram of the first CsPbBr<sub>3</sub>-based OLED sample.<sup>[11, 12]</sup>

- The hole injection is performed by a PEDOT:PSS and poly-TPD layer of total thickness of 90 nm
- The Alq<sub>3</sub>-OXD7 shows superior performance as electron transport system, because the OXD-7 probably has a strong hole blocking ability.
- An optional PMMA spacer is added to the system for better film growth.

#### Introduction of CsPbBr<sub>3</sub> in an OLED stack

The CsPbBr3 device's color is as expected a green-cyan tone.

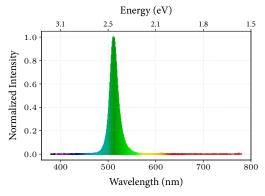

Figure 11: Electroluminescent spectrum of the CsPbBr<sub>3</sub> based OLEDs.

- The peak at 513 nm has a FWHM<sup>a</sup> of approximately 20 nm, which is quite good for application in display devices
- Groups of references 12–14 get very similar electroluminescent spectra.

<sup>&</sup>lt;sup>a</sup>FWHM = full width half maximum

### Introduction of CsPbBr3 in an OLED stack

The CsPbBr<sub>3</sub> device is not performing very well, when considering the high quantum yield of CsPbBr<sub>3</sub> quantum dots in general. <sup>[15]</sup>

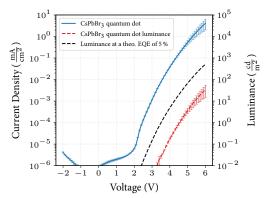

Figure 12: Current density and luminance versus driving voltage characteristics of the CsPbBr<sub>3</sub>-based OLEDs.

- The luminance is an order of magnitude smaller than for an ideal fluorescent emitter.<sup>a</sup>
- The currents are two orders of magnitude higher than the ones for the Ir(ppy)<sub>3</sub> based device.
- The device starts degrading within seconds when driven at voltages higher than 6 volts.

 $<sup>^{\</sup>rm a}{\rm A}$  theoretical device with a constant EQE of 5 %, the same voltage-current dependence, and the same emission spectrum.

# Influence of PMMA in the CsPbBr<sub>3</sub>-OLED

The PMMA improves the EQE of the devices by a factor of 1.5.

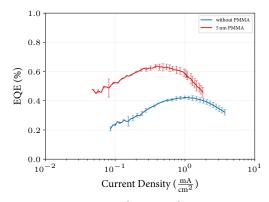

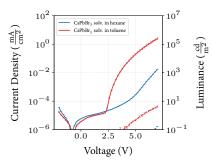

Figure 13: EQE versus driving voltage characteristics of the CsPbBr<sub>3</sub>-based OLEDs.

- The PMMA layers leads to an increased EQE.
- However, the EQEs of both devices are an order of magnitude lower than the theoretical limit.

### Performance of tolene-free CsPbBr<sub>3</sub>-OLEDs

Hexane based samples achieve higher efficiencies.

0.5CsPbBr, solv, in hexane 0.4EQE (%) 0.3 0.1 0.0 - $10^{-2}$  $10^{0}$  $10^{-1}$  $10^{1}$  $10^{2}$ Current Density  $(\frac{mA}{cm^2})$ 

versus driving voltage characteristics of the hexane-CsPbBr<sub>3</sub>-based OLEDs.

Figure 14: Current density and luminance Figure 15: EQE versus driving voltage characteristics of the hexane-CsPbBr3-based OLEDs.

• The hexane based QDs show worse injection, while showing higher EQE.

Introduction

SCIENTIFIC CONSCIENT

- 2 Development of a suitable hole injection site
- 3 Design of OLED's based on the (MA)PbI<sub>3</sub> perovskite
  - Synthesis and characterization of (MA)PbI<sub>3</sub> layers
  - Characterization of OLEDs based on (MA)PbI<sub>3</sub> perovskite

- Summary and Outlook
- 6 Additional Slides for Disscussion

#### Summary

Perovskite based OLEDs could be created. However the efficiency is very low.

- (MA)PbI<sub>3</sub> based OLEDs:
  - Nearly infrared light is emitted.
  - Highly depending on environmental conditions during manufacturing.
  - Very poor performance.
- CsPbBr<sub>3</sub> based OLEDs:
  - Green-cyan color, small peak width.
  - ▶ Impaired hole injection, which is a major shortcoming in present devices.
  - Performance depending on used solvent.

#### Outlook

 $(MA)PbI_3$  based OLEDs will be dropped.  $CsPbBr_3$  based OLEDs, need further investigation.

- (MA)PbI<sub>3</sub> based OLEDs:
  - ► Switching to (MA)PbBr<sub>3</sub> to get actual optical devices.
  - ► For further investigation as IR-diode the intial results were too poor and the required equipment is not present.
- CsPbBr<sub>3</sub> based OLEDs:
  - Some optical measurement of the CsPbBr<sub>3</sub> layer may help to find other limiting factors.
  - ► Easing the hole-injection with new or new combination of the HILs
  - ▶ New batches of CsPbBr<sub>3</sub> with different solvents and ligand density should help finding a suitable hole injection system.
  - ▶ An inverted device, where ITO-ZnO is used for electron injection and hole injection can be done by well-known evaporated organics.

# Thousand thanks to:

- Professor Wolfgang Brütting.
- Manuel Engelmayer, Florian Graßl and Thomas Lampe, for mentoring.
- Matthew Jurow (University of Berkeley) for supplying the CsPbBr<sub>3</sub> quantum dot solutions.
- All other colleagues of the Chair of Experimental Physics IV.
- and You for Your attention.

### Hole Only Devices

The hole conductivity is greatly increased by CsPbBr<sub>3</sub> deposition.

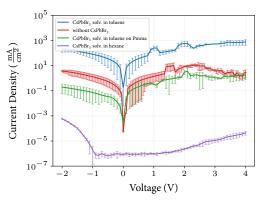

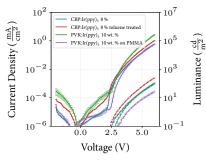

Figure 16: Current density versus driving voltage characteristics of hole only devices.

- The CsPbBr<sub>3</sub> solved in toluene device a resistance of only 120 Ω.
- PMMA intervenes, so that the resistance is higher than it is for the CsPbBr<sub>3</sub> free.
- Hexane based CsPbBr<sub>3</sub> devices show extremely low hole conductivity.

# Solution Processed Ir(ppy)<sub>3</sub>

The toluene susceptibility is still present, but it enhances the efficiency.

| Complete (ppy), 8% | CBP-lift(ppy), 8% | CBP-lift(ppy), 8% toluces treated | PVK-lift(ppy), 10 wt. % | PVK-lift(ppy), 10 wt. % | PVK-lift(ppy), 10 wt. % on PMMA | PVK-lift(pp

Figure 17: Current density versus driving voltage characteristics of solution processed Ir(ppy)<sub>3</sub> based devices.

Figure 18: Current density versus driving voltage characteristics solution processed Ir(ppy)<sub>3</sub> based devices.

• PMMA does not increase the EQE, but toluene on does.

### Switching ETL

TBPi increases the current and the luminance.

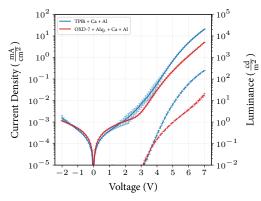

Figure 19: Current density versus driving voltage characteristics of TPBi based devices.

- TPBi leads to higher currents.
- But it also leads to overproportionally more luminance.
- This matter of facts contradicts the with a bad hole injection.
